Non-coding genetic variation is a major driver of phenotypic diversity, but functional interpretation is challenging. To better understand common genetic variation associated with brain diseases, we defined non-coding regulatory regions for major cell types of the human brain. Whereas psychiatric disorders were primarily associated with variants in transcriptional enhancers and promoters in neurons, sporadic Alzheimer's disease (AD) variants were largely confined to microglia enhancers. Interactome maps connecting disease-risk variants in cell type-specific enhancers to promoters revealed an extended microglia gene network in AD. Deletion of a microglia-specific enhancer harboring AD-risk variants ablated *BIN1* expression in microglia but not in neurons or astrocytes. These findings revise and expand the genes likely to be influenced by non-coding variants in AD and suggest the probable cell types in which they function.

The central nervous system is a complex organ consisting of diverse and highly interconnected cells. Single cell sequencing technologies have advanced our understanding of the molecular phenotypes of human neurons, microglia, astrocytes, oligodendrocytes and other cell types that reside within the brain (1–3), but the transcriptional mechanisms that control their developmental and functional properties in health and disease remain less well understood. Genome-wide association studies (GWASs) provide a genetic approach to identify molecular pathways involved in complex traits and diseases by defining associations between genetic variants and phenotypes of interest (4, 5). Large-scale GWASs have discovered hundreds of single nucleotide polymorphisms (SNPs) associated with the risk of neurological and psychiatric disorders. The vast majority of these disease-risk genetic variants are located in non-coding regions of the genome (5). The causal variants and the specific cell type(s) in which the disease-risk variants may be active is often unclear. GWAS-identified risk variants in non-coding regions of the genome can exert

phenotypic effects through perturbation of transcriptional gene promoters and enhancers (4). Enhancers are short regions of DNA that bind transcription factors to enhance mRNA expression from target promoters. Clusters of multiple enhancers, referred to as super enhancers, are particularly important in driving the expression of cell identity genes (6). Unique enhancer repertoires underly particular patterns of gene expression and enable cell type-specific responses (7). The activity of enhancers depends on three-dimensional enhancer-promoter interactions (8), however, the enhancer-promoter interactome of different brain cell types in vivo remain largely unknown.

To characterize transcriptional regulatory elements within different cell types of the human brain, PU.1⁺ microglia, NEUN⁺ neuronal, OLIG2⁺ oligodendrocyte and NEUN^{neg} LHX2⁺ nuclei were isolated from resected cortical brain tissue from 6 individuals by fluorescent activated nuclei sorting (fig. S1, A and B, and table S1). Cell type-specific populations of 200k nuclei were subjected to ATAC-seq, which identifies

open regions of chromatin (9); and cell type-specific populations of 500k nuclei were subjected to H3K27ac and H3K4me3 ChIP-seq, which predominantly identify active chromatin regions and promoters, respectively (10, 11). These datasets clustered according to cell type of origin and exhibited cell type-specific patterns (Figs. 1A and fig. S1, C to E). Promoter H3K27ac signal correlated with gene expression of the corresponding cell type more closely than ATAC-seq and H3K4me3 ChIP-seq (fig. S1F) (12). Promoters associated with cell type signature genes preferentially exhibited corresponding H3K27ac profiles (fig. S1G) (13). Oligodendrocyte nuclei contain a low number of oligodendrocyte precursor cells, while neuronal nuclei represent a mixture of excitatory and inhibitory subtypes (fig. S1G). ATAC-seq and H3K27ac ChIP-seq profiles generated from PU.1 nuclei were highly correlated with those previously defined in ex vivo microglia (fig. S1, C and D) (14). Promoter H3K27ac signal was increased at microglia signature genes compared to genes associated with other myeloid populations (fig. S1H) (15). Cell type-specific promoter activity defined by differential H3K27ac mirrored cell type patterns of gene expression (12), as well as ATAC-seq and H3K4me3 enrichment, and were associated with gene ontologies representative of each cell type (fig. S2, A to D, and table S2).

We identified putative active promoters and enhancers in each cell type and found a one-to many relationship between promoters and enhancers (8). Whereas active promoters are largely shared between cell types (Fig. 1B), a relatively small fraction of active enhancers overlap between cell types (Fig. 1C), indicating that cell type specificity is mainly captured within the enhancer repertoire. Most bulk brain enhancer regions identified by PsychENCODE overlapped with the nuclei cell type enhancers (94%) (13). However, analysis of cell-specific nuclei expanded the total number of putative brain enhancers by 87%.

To determine the enrichment of genetic variants associated with complex traits and diseases in cell type-specific regulatory regions, we performed linkage disequilibrium score (LDSC) regression analysis of heritability (16). LDSC utilizes GWAS summary statistics to determine whether genetic heritability for a trait or disease is enriched for SNPs within genome annotations while accounting for linkage disequilibrium. We obtained GWAS summary statistics for neurological and psychiatric disorders and neurobehavioral traits (17) (table S3). We found a strong enrichment of heritability for variants within neuronal enhancers and promoters for all psychiatric disorders and behavioral traits (Fig. 1D), which was substantially lower in PsychENCODE bulk brain enhancers (Fig. 1D) (13). In contrast, AD SNP heritability was most highly enriched in microglia regulatory elements (Fig. 1D), specifically microglia enhancers (18-23).

De novo motif analyses at open chromatin within

enhancers identified transcription factor binding motifs associated with each cell type (fig. S3). In addition, H3K27ac-defined active promoters identified 288 human transcription factors that were active in a cell type-specific manner (fig. S4 and table S2) (24), several of which have been associated with disease (fig. S5 and table S4). Integrating cell type-specific transcription factors with enhancer motifs of the corresponding cell type identifies major drivers of cell ontogeny.

The relationship between promoters and distal regulatory regions for different cell types in the brain is largely unknown. We utilized proximity ligation-assisted ChIP-seq (PLAC-seq) in which proximity ligation preceded an enrichment for active promoters by H3K4me3 ChIP-seq (25). Chromatin loops were identified between active promoters and distal regulatory regions in microglia, neurons and oligodendrocytes (26). An example is the *SALL1* locus, which has interactions to cell type-specific enhancers, including chromatin loops to a microglia-specific super-enhancer (Fig. 2A). There were 219,509 significant unique interactions across cell types, and replicates clustered according to origin (fig. S6, A and B, and table S5). A strong H3K4me3 signal did not dictate that an interaction will occur (fig. S6C), suggesting that PLAC-seq captures a unique dimension of the chromatin conformation.

A subset of chromatin interactions was significantly more active in each cell type and colocalized with increased ATAC-seq, H3K27ac and H3K4me3 ChIP-seq signal in a cell type-specific manner (Fig. 2B and fig. S6D). Active promoters linked to microglia, neuronal and oligodendrocyte enriched interactions were associated with gene ontology terms representative of each cell type, supporting the ability of the PLAC interactome to annotate cell type-specific promoter-enhancer interactions (Fig. 2C).

We identified 2,954 super-enhancers in microglia, neurons and oligodendrocytes, of which 83% had PLAC-interactions and were linked to promoters with elevated H3K27ac levels compared to promoters linked to regular enhancers (fig. S7, A and B). Many super-enhancers harbored GWAS disease-risk variants and were connected to cell type-specific genes, suggesting that a subset of GWAS variants act on super-enhancers to affect gene expression (fig. S7A and table S6).

To better understand AD genetics and the microglia interactome, we distinguished likely causal variants from those in linkage disequilibrium by applying fine mapping and identified 261 credible set variants (18). In many instances, such as the *BINI*, *PICALM*, and *SORL1* loci, the fine mapped variants overlapped with microglia-specific enhancers that were PLAC-linked to corresponding gene promoters (Fig. 3A). Next, we determined PLAC-interactions between active promoters and AD-risk credible set variants (19) and identified forty-one genes that were linked to these variants across cell

types (fig. S8). Twenty-five of the PLAC-linked AD-risk genes were identified in microglia, of which 14 were not detected in the other cell types (Fig. 3B and fig. S8). A broader set of 134 putative risk genes were identified by applying the same analysis to all genome-wide significant variants found in two AD GWASs (figs. S8 and S9, A and B, and table S7) (18, 19).

Protein-protein interaction (PPI) network analysis showed that microglia AD-risk genes identified by PLAC-seq were highly connected with GWAS-assigned genes and centered around *APOE*, whereas PPI networks for neurons and oligodendrocytes were smaller in scope (fig. S9, C to E). Microglia AD-assigned genes were associated with gene ontology terms for immune function, whereas gene ontology terms for amyloid-beta processing were associated with neurons, microglia and oligodendrocytes (fig. S9F).

PLAC-interactions altered interpretation of AD-risk variants according to three features. First, we found AD-risk variants that were linked to more distal active promoters and not the closest gene promoter. An example is the *SLC24A4* locus, which has AD-risk variants that were connected to the proximal active promoters of *ATXN3*, *TRIP11* and *CPSF2*, but not to *SLC24A4* (Fig. 3C). Second, we observed enhancers harboring AD-risk variants that were PLAC-linked to active promoters of both GWAS-assigned genes and an extended subset of genes not assigned to GWAS loci. An example is the *CLU* locus, which has PLAC-linked AD-risk variants to the GWAS-assigned genes *CLU* and *PTK2B*, and an extended set of genes *TRIM35*, *CHRNA2*, *SCARA3* and *CCDC25* (Fig. 3D). Last, we identified cell type-specific enhancers harboring AD-risk variants that were linked to genes expressed in multiple cell types, implicating cell type-specific disease susceptibility. Examples are the *PICALM* and *BIN1* loci, which, despite being expressed in multiple cell types (12), have microglia-specific enhancers harboring AD-risk variants (Figs. 3E and 4A).

The *BIN1* microglia-specific enhancer is PLAC-linked to the *BIN1* promoter (Fig. 4A), binds to PU.1 (14) and contains the AD-risk variant rs6733839, which has the second highest AD-risk score after *APOE* and was fine-mapped as a casual variant (Fig. 3A). Functionality of this microglia-specific enhancer was validated by CRISPR/Cas9-mediated deletion of a 363 bp region in two human pluripotent stem cell (PSC) lines (fig. S10, A to C). PSC control (*BIN1*^{control}) and *BIN1* enhancer deletion (*BIN1*^{enh_del}) lines had normal karyotypes (fig. S10D) and were differentiated into microglia, neurons and astrocytes (Fig. 4B and figs. S11, A to D, and S12, A and B). Gene expression analysis of *BIN1*^{control} and *BIN1*^{enh_del} lines in PSC and PSC-derived microglia, neurons and astrocytes showed high correlation between samples, with clustering according to cell type (fig. S12, C and D). However, gene expression of *BIN1* was nearly absent in the *BIN1*^{enh_del} PSC-derived microglia, whereas *BIN1* expression in *BIN1*^{enh_del} PSCs and PSC-derived neurons and astrocytes were equivalent to *BIN1*^{control}

cells (Fig. 4C, fig. S12E, and table S8). Western blot confirmed *BIN1* protein in *BIN1*^{control} PSCs and PSC-derived microglia, neurons and astrocytes (Fig. 4, D and E, and fig. S12F). *BIN1* expression was unchanged in *BIN1*^{enh_del} PSC-derived microglia precursor hematopoietic stem cells, indicating that microglia derivation was unaffected (fig. S12F). However, *BIN1* was dramatically reduced in *BIN1*^{enh_del} microglia and not neurons and astrocytes (Fig. 4, D and E). This finding that the most significant GWAS risk allele associated with *BIN1* resides in a microglia-specific enhancer provides a rational for further investigation of its function in these cells (27).

The present studies provide evidence that identification of cell type-specific promoter-enhancer interactomes enables substantial advances in interpretation of GWAS risk alleles associated with neurological and psychiatric diseases and establish a new resource for this purpose. Major goals will be to extend these approaches to diseased tissues and refine nuclear sorting protocols to interrogate enhancer landscapes of informative cell subsets, such as amyloid plaque-associated microglia (28). Disease-specific regulatory elements are likely to be influenced by genetic variation, which due to our limited sample size may partly explain the lack of overlap of a subset of risk alleles with the current regulatory atlases. The acquisition of more samples will provide further opportunity to evaluate inter-individual variation on enhancer selection and function. We expect that these approaches will provide qualitatively new insights into disease mechanisms that may be of value in developing new approaches for prevention and treatment.

ACKNOWLEDGMENTS

We thank J. Collier, L. Van Ael, D. Skola and M. L. Gage and M. Gymrek. **Funding:** Support was provided by NIH grants RF1 AG061060-01, R01 AG056511-01A1, R01 AG057706-01, a Cure Alzheimer's Fund Gifford Neuroinflammation Consortium, and UCSD Shiley-Marcos ADRC 1P30AG062429. A.N. was supported by the Alzheimer's Association (AARF-18-531498) and the Altman Clinical & Translational Research Institute at UCSD (National Center for Advancing Translational Sciences, NIH KL2TR001444). I.R.H. was supported by the VENI research program, which is financed by the Netherlands Organization for Scientific Research. N.G.C. was funded by NIH K08 NS109200-01 and The Hartwell Foundation. C.Z.H. is supported by the Cancer Research Institute Irvington Postdoctoral Fellowship Program. C.O. was funded by NIHNCI CCSG: P30 014195 and S10-OD023689. Salk facilities are supported by the Salk Cancer Center (NCI grant: P30-CA014195). F.H.G. was supported by the JPB Foundation, The Engman Foundation, The AHA/ Allen Award, and the Dolby Foundation. J.B.B. and R.A.S. were supported by AG062429-01. **Author contributions:** A.N., N.G.C., J.C.M.S., and C.K.G. conceived the study. N.G.C. coordinated tissue acquisition. D.D.G., and M.L.L. resected brain tissue. A.N., C.K.N., M.P.P. and D.G. isolated nuclei and cells. N.G.C., M.P., J.X., Y.W., Z.K. and C.O. performed PSC experiments. A.N., M.Y. and R.H. prepared sequencing libraries. I.R.H., A.N., and Z.S. analyzed datasets. A.N., I.R.H., C.K.G. wrote the manuscript, with contributions from N.G.C., C.Z.H., J.C.M.S., M.G.R., F.H.G. and B.R. **Competing interests:** B.R. is co-founder of Arima Genomics, Inc, which sells Hi-C and PLAC-seq kits. **Data and materials availability:** Data available on dbGap (accession number: phs001373.v2.p1). UCSC browser session: https://genome.ucsc.edu/s/nottalexi/glassLab_BrainCellTypes_hg19.

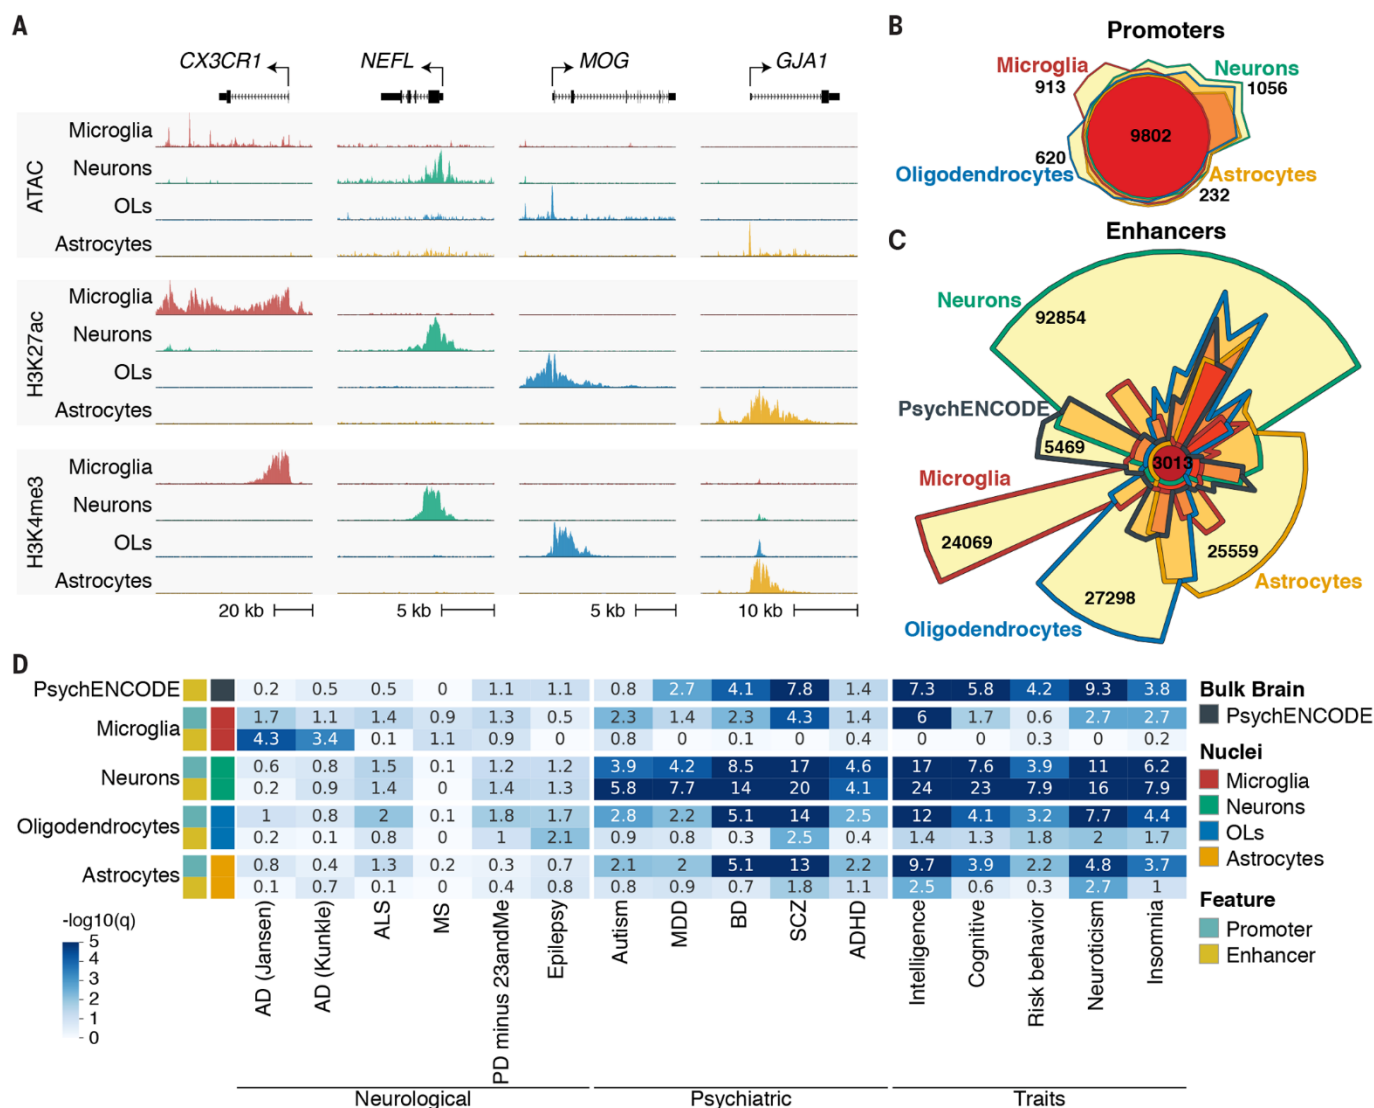

Fig. 1. Cell type-specific genomic regulatory region enrichments for GWAS-risk variants for brain disorders and behavioral traits. (A) UCSC browser of ATAC-seq (top panel), H3K4me3 (middle panel) and H3K27ac ChIP-seq (bottom panel) for brain nuclei populations. Shown is a representative gene for microglia (*CX3CR1*), neurons (*NEFL*), oligodendrocytes (*MOG*) and astrocytes (*GJA1*). **(B)** Chow-Ruskey plot of promoter regions defined for cell populations. **(C)** Chow-Ruskey plot of enhancer regions defined for cell populations and PsychENCODE enhancers defined using bulk brain. **(D)** Heatmap of LDSC analysis for genetic variants associated with brain disorders and behavior traits displayed as $-\log_{10}(q)$ value for significance of enrichment for promoter and enhancer regions of cell populations and PsychENCODE bulk brain enhancers. OL, oligodendrocytes.

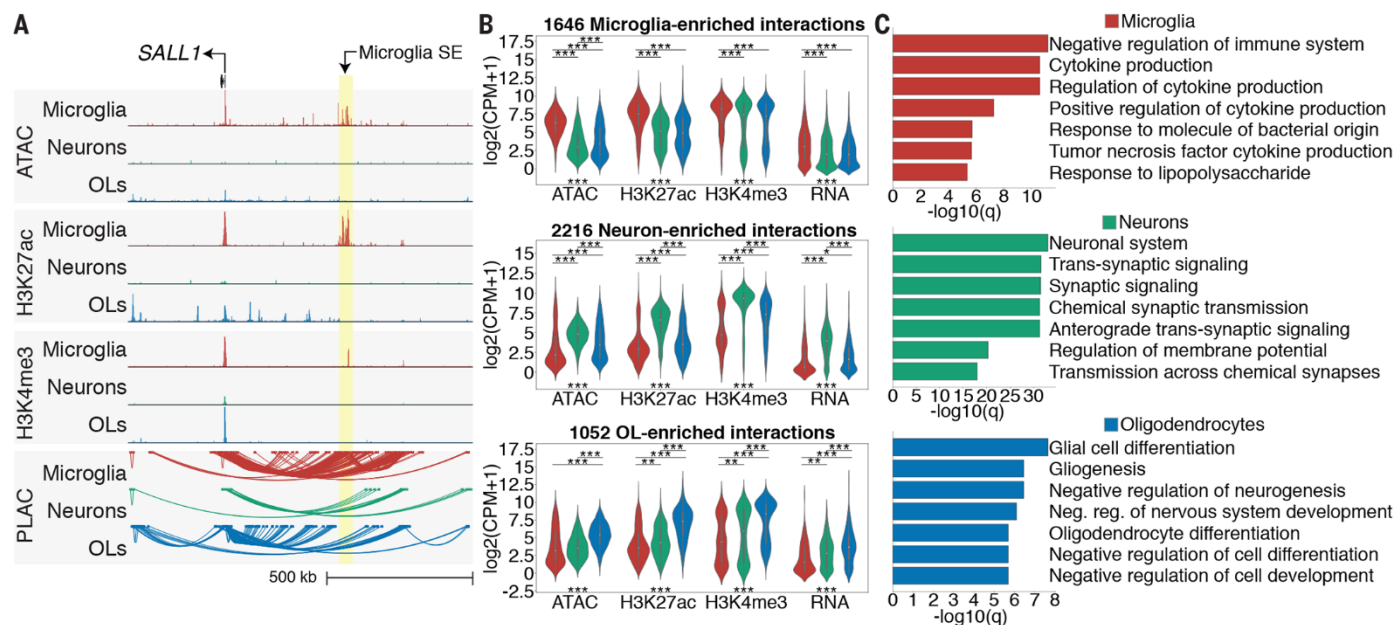

Fig. 2. Chromatin loops link promoters to active gene regulatory regions. (A) UCSC browser of ATAC-seq, and H3K27ac and H3K4me3 ChIP-seq, and PLAC-seq loops at the *SALL1* locus. The microglia-specific super-enhancer is associated with microglia interactions (highlighted yellow). (B) Violin plots of ATAC-seq, H3K27ac, H3K4me3 ChIP-seq and RNA-seq log₂(CPM) values at PLAC-seq up-regulated interactions shown in fig. S7B for microglia, neurons and oligodendrocytes; *** = $P < 1e-12$; ** = $P < 1e-5$; * = $P < 1e-3$. Kruskal-Wallis-between group test. (C) Metascape enrichment analyses of active genes identified at PLAC-seq up-regulated interactions shown in fig. S6D for microglia, neurons and oligodendrocytes shown as -log₁₀(q) values.

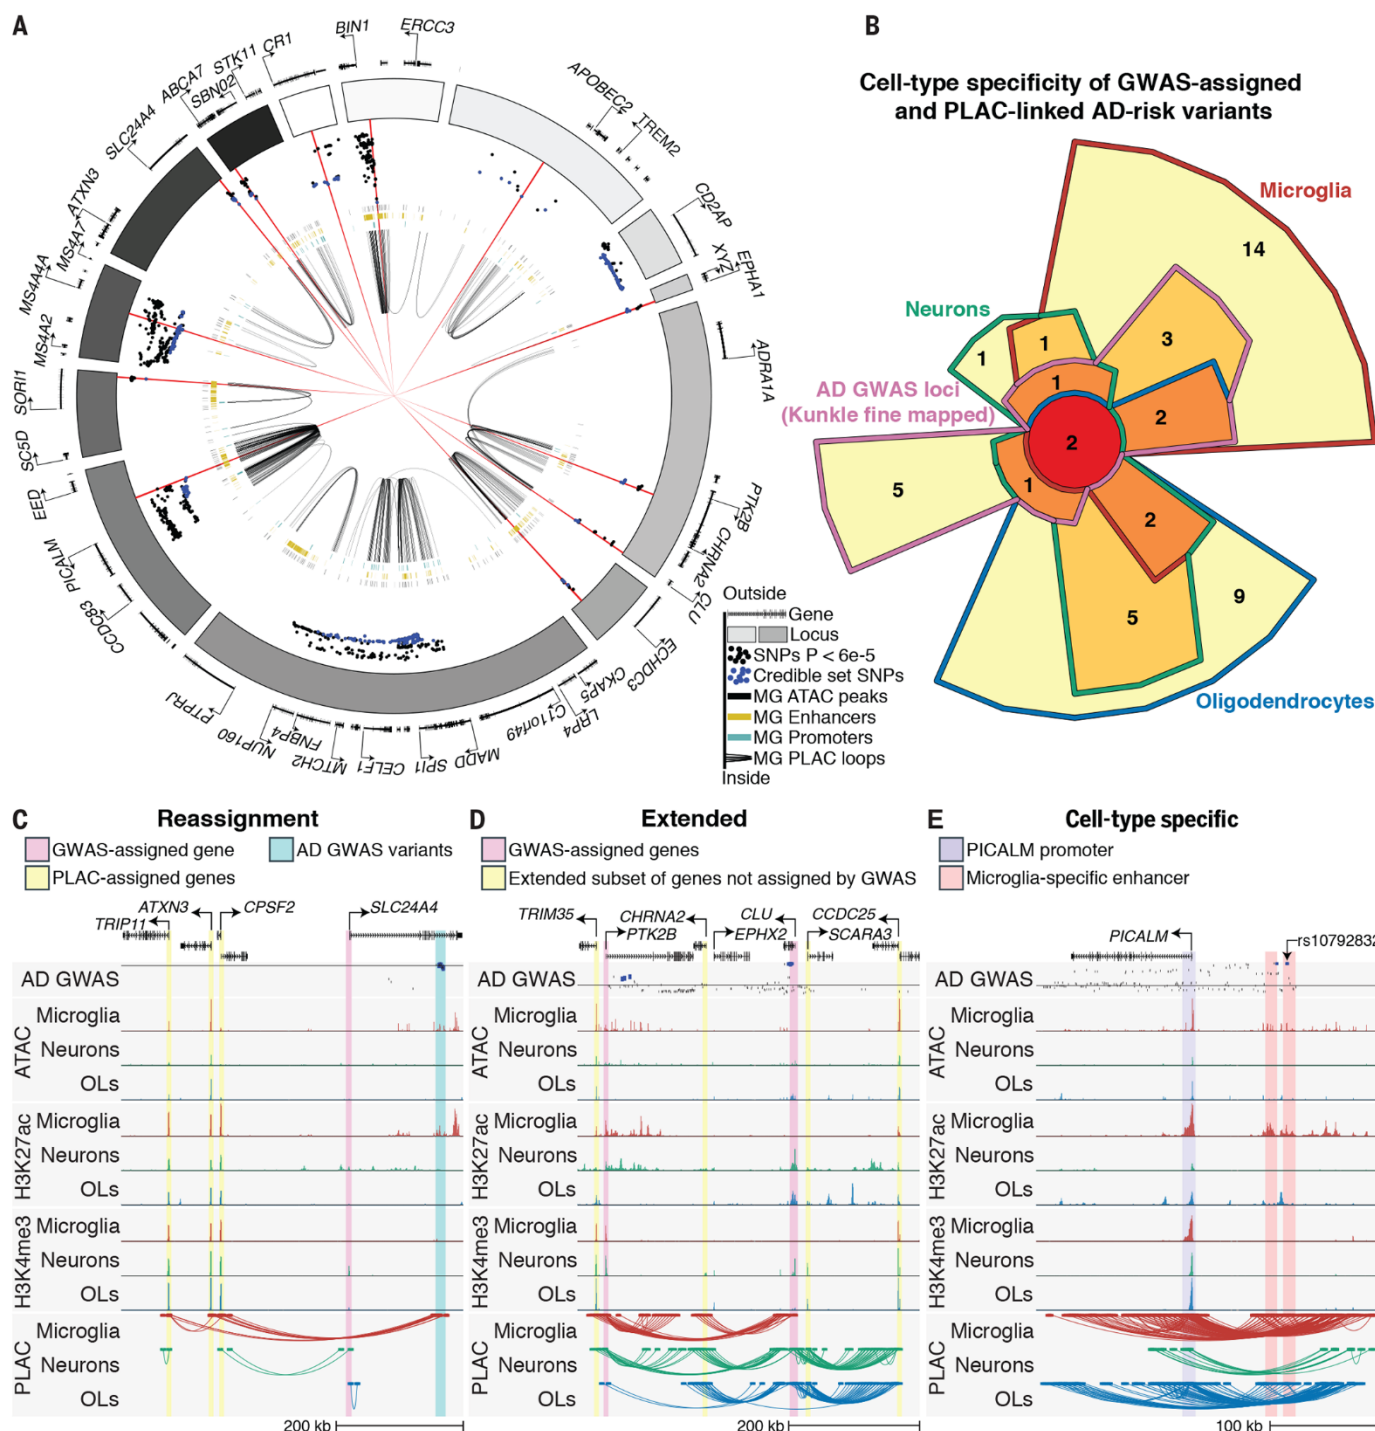

Fig. 3. Expanded gene network of AD-risk loci. (A) Circos plot of AD GWAS loci, showing microglia enhancers (gold bars), promoters (turquoise), open chromatin regions (black bars) and PLAC-seq interactions (black loops). Dots show z-score values of high-confidence AD variants identified by fine mapping (Kunkle, stage 1) with \log_{10} p-value $< 6e-5$ (18). Blue dots represent z-score values of the credible set of AD SNPs (95% confidence); red lines show 15 high-confidence AD SNPs with a posterior probability > 0.2 . (B) Chow-Ruskey plot of genes that are GWAS-assigned and PLAC-seq linked to AD-risk credible set variants in microglia, neurons and oligodendrocytes. (C to E) UCSC browser of interactions at AD-risk loci demonstrating (C) reassignment of GWAS-assigned genes, (D) extension of GWAS-assigned genes and (E) cell type-specific gene regulatory regions. The AD GWAS track shows meta-analysis p-values of stage 2 variants (18); line indicates p-value = $5e-8$; blue dots are fine mapped 95% credible set variants.

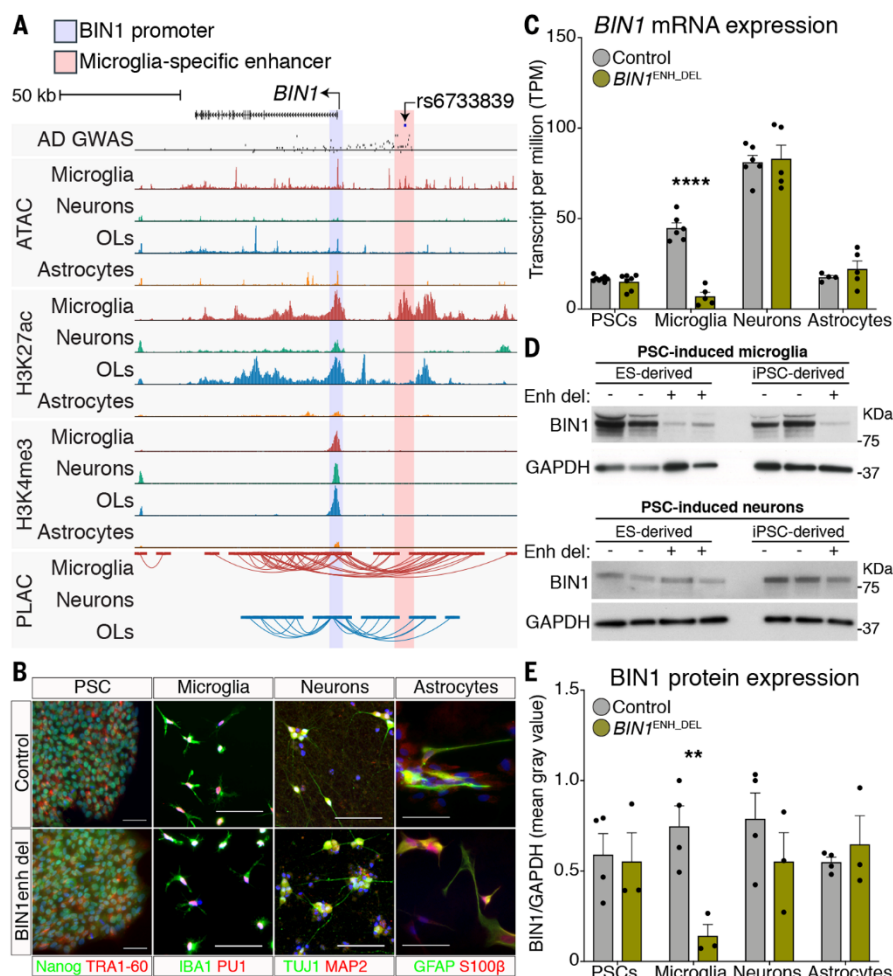

Fig. 4. Deletion of a microglia-specific enhancer harboring a lead AD-risk variant affects microglia *BIN1* expression. (A) UCSC browser of the *BIN1* locus showing AD-risk variants, ATAC-seq, H3K27ac, H3K4me3 ChIP-seq and PLAC-seq in brain cell types. Shared active promoter region, highlighted pink; microglia-specific enhancer region, highlighted in yellow. The AD GWAS track shows meta-analysis p-values of stage 2 variants (18); line indicates p-value = 5e-8; blue dots are fine mapped 95% credible set variants. (B) Immunohistochemistry of PSCs, microglia, neurons and astrocytes in control and *BIN1^{enh_del}* lines stained for the indicated cell lineage markers. (C) *BIN1* gene expression in control and *BIN1^{enh_del}* PSCs (N = 8,7), microglia (N = 6,5), neurons (N = 6,5) and astrocytes (N = 4,5) as RNA-seq TPM. **** Benjamini and Hochberg adjusted p-value < 0.0001. (D) Western blot of *BIN1* and GAPDH in control and *BIN1^{enh_del}* PSC-derived microglia (top) and neurons (bottom). (E) Protein expression of *BIN1* in control and *BIN1^{enh_del}* PSCs, microglia, neurons and astrocytes determined as Western blot *BIN1*/GAPDH mean gray intensity. N = 4 controls, 3 *BIN1^{enh_del}* per cell type. ** unpaired two-tailed *t* test p-value < 0.01.

Brain cell type–specific enhancer-promoter interactome maps and disease risk association
